May 14, 2014, Boulder, CO

Development & deployment of offshore WE

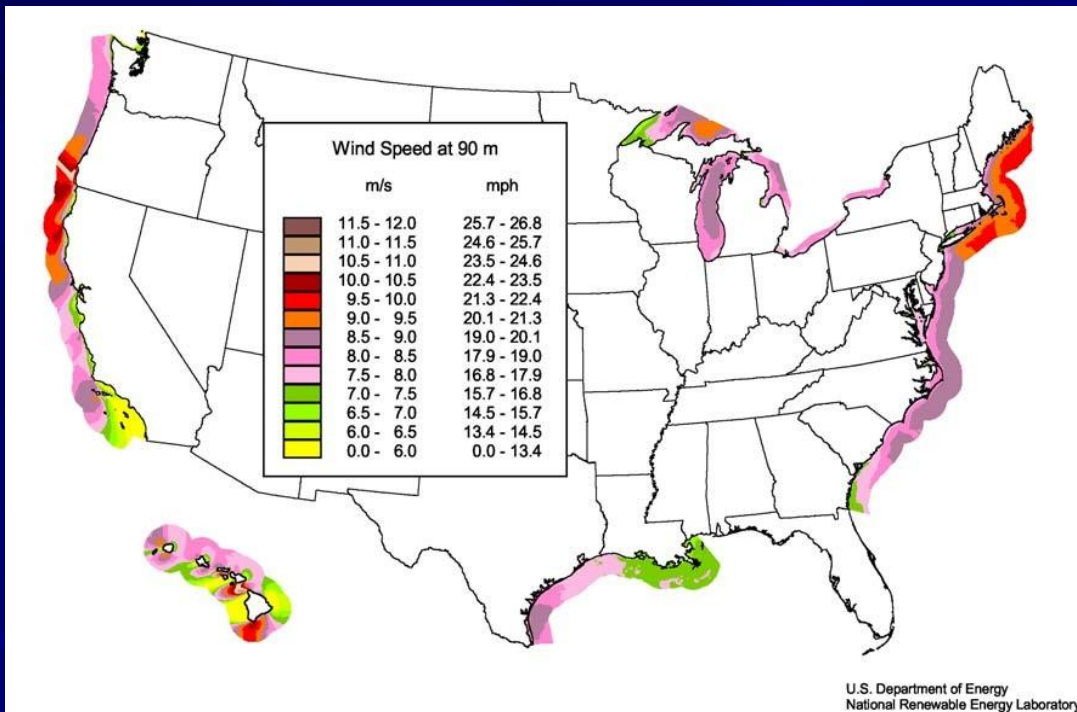

US offshore WE Goal:
54 GW of wind generating capacity
by 2030, at a cost of energy of
\$0.07/ kWh.

Shortage of data
on the wind flow at turbine rotor
heights drives up the costs of the
installation, operations, and
maintenance of wind projects

Models are potentially important tools
in providing offshore winds

Modeled wind resources

In the absence of measurements at turbine levels, the accuracy and fidelity of model output is unknown

U.S. offshore wind speed estimates at 90-m height

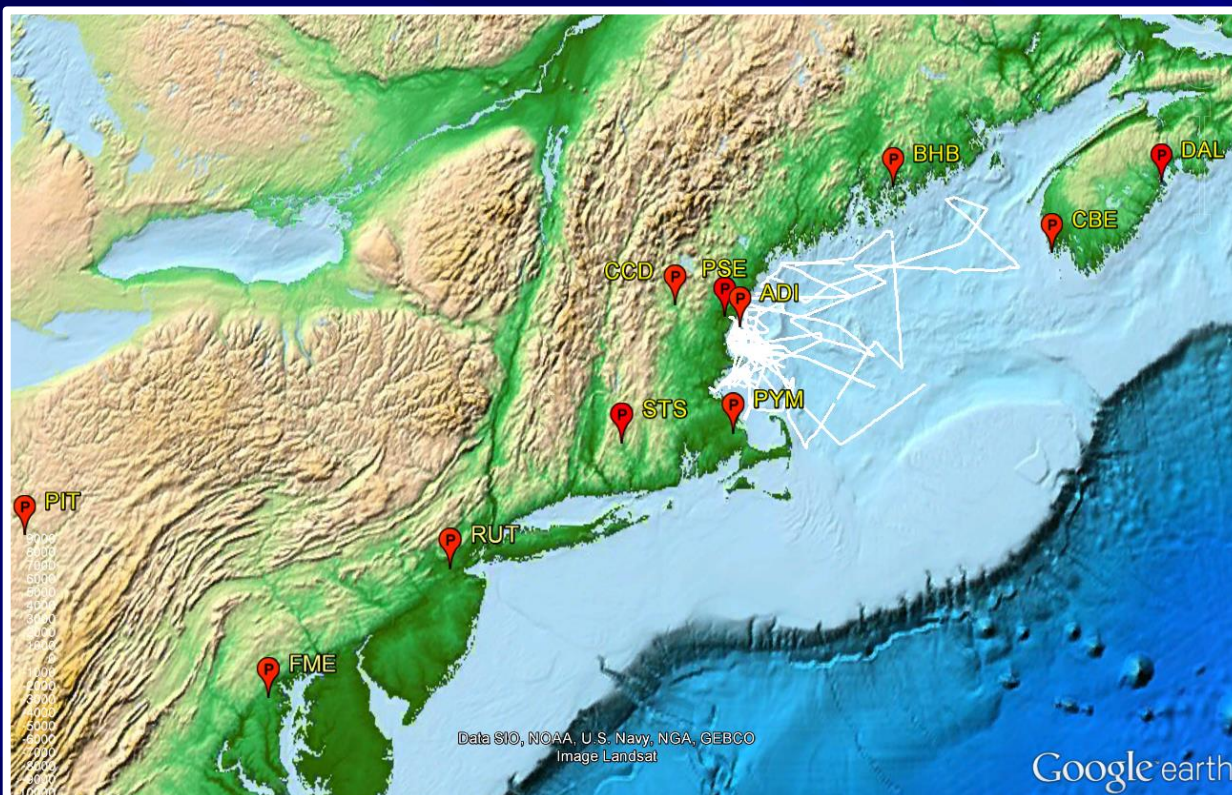

(DOE Report, 02/2011)

Average 80-m wind speed over the Gulf of Maine in 2012 – 2013

(DOE Report, 04/2014)

Prediction of Offshore Wind Energy Resources (POWER) - 2013

Objectives

- Use ship-borne lidar measurements to evaluate NOAA/NCEP forecast model skill in predicting boundary-layer winds
- Assess the impact of inland wind profiler data assimilation on the accuracy of hourly updated weather model forecasts
- Determine spatial variability of marine winds

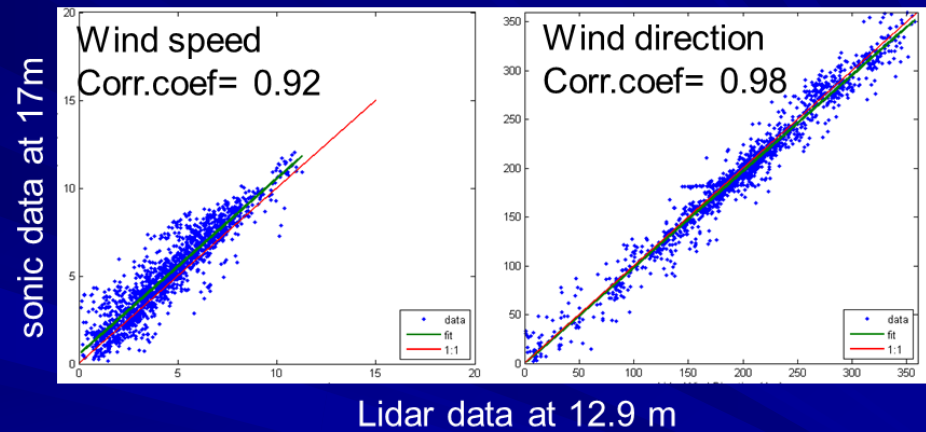

The High Resolution Doppler Lidar

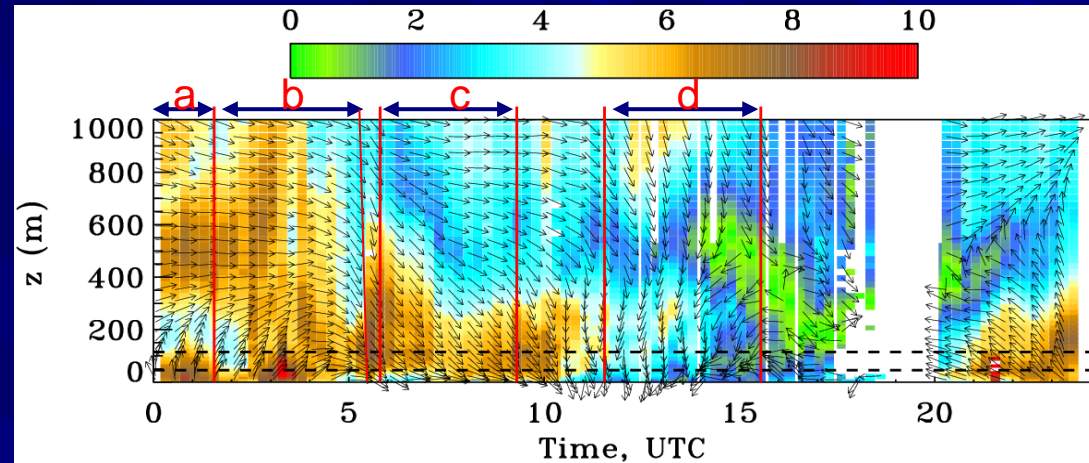

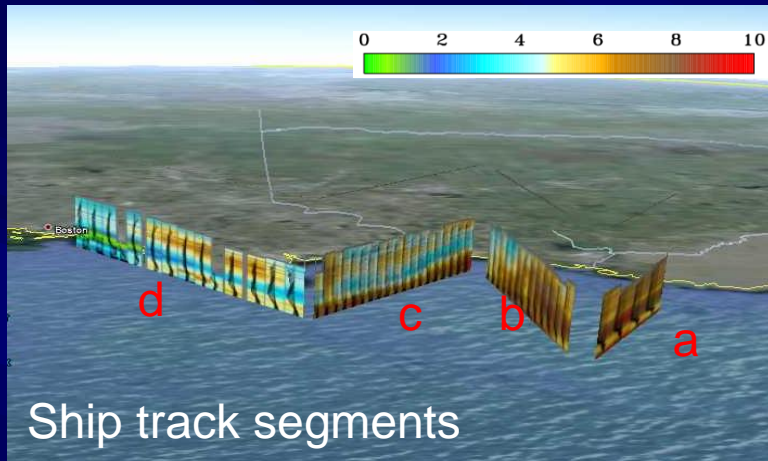

Characteristics	HRDL
Wavelength	2.02 μm
Pulse energy	2.0 mJ
Pulse rate	200 Hz
Range resolution	30 m
Velocity precision	$\sim 10 \text{ cm s}^{-1}$
Time resolution	0.5 s
Minimum range	189 m
Maximum range	3-8 km

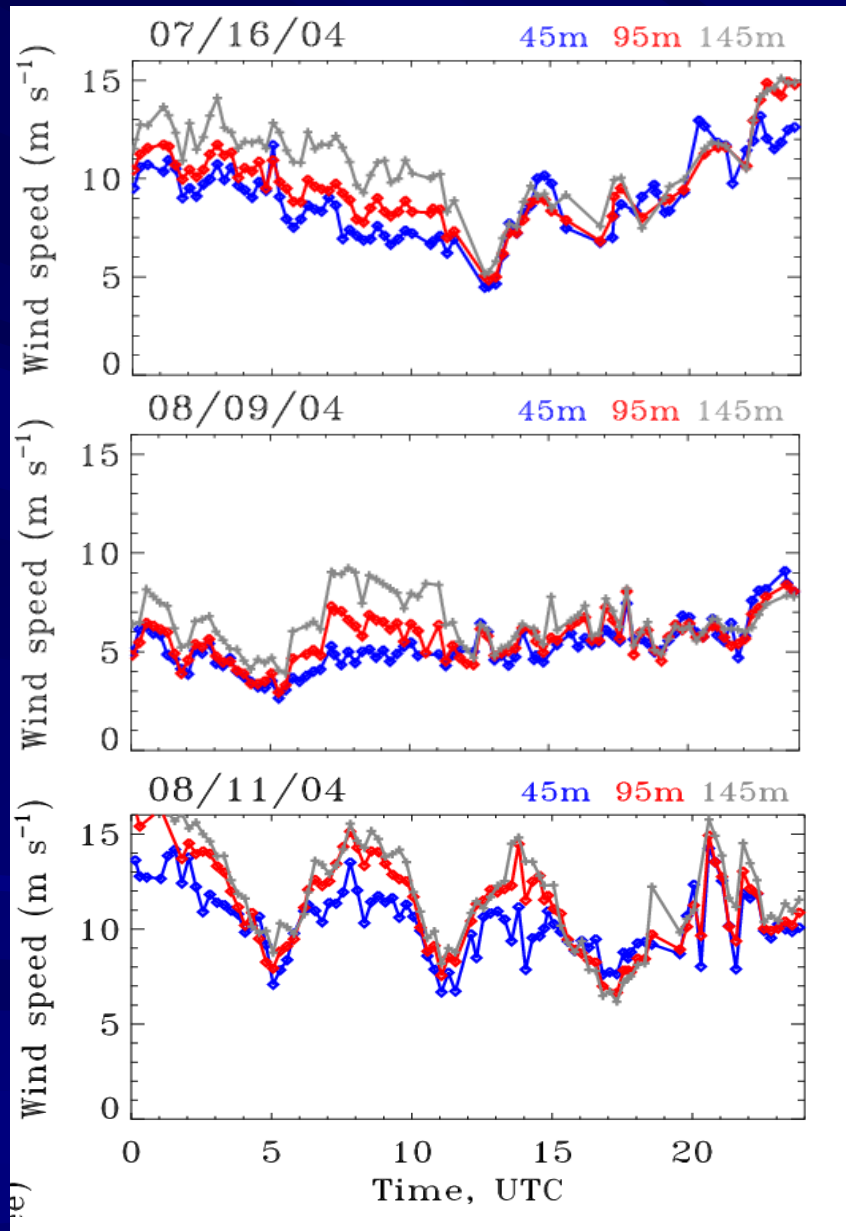

Pointing angle error
 $< 0.5^\circ$ - normal sea
 $< 1^\circ$ - rough sea

Spatial and temporal variability of lidar-measured winds

Heights of measurements and model outputs

Models used in the study

- *High Resolution Rapid Refresh*
- *Rapid Refresh*
- *Contiguous United States*
- *North American Mesoscale*

Study periods: July 10-17 and August 6-12

- Possibly in the same area
NEAQS 2004 was designed to track urban pollution plumes
- Broad coverage
close to the shore and farther out in the ocean
- Variety of atmospheric conditions
strong and weak winds, ramps, LLJ, fog, and rain

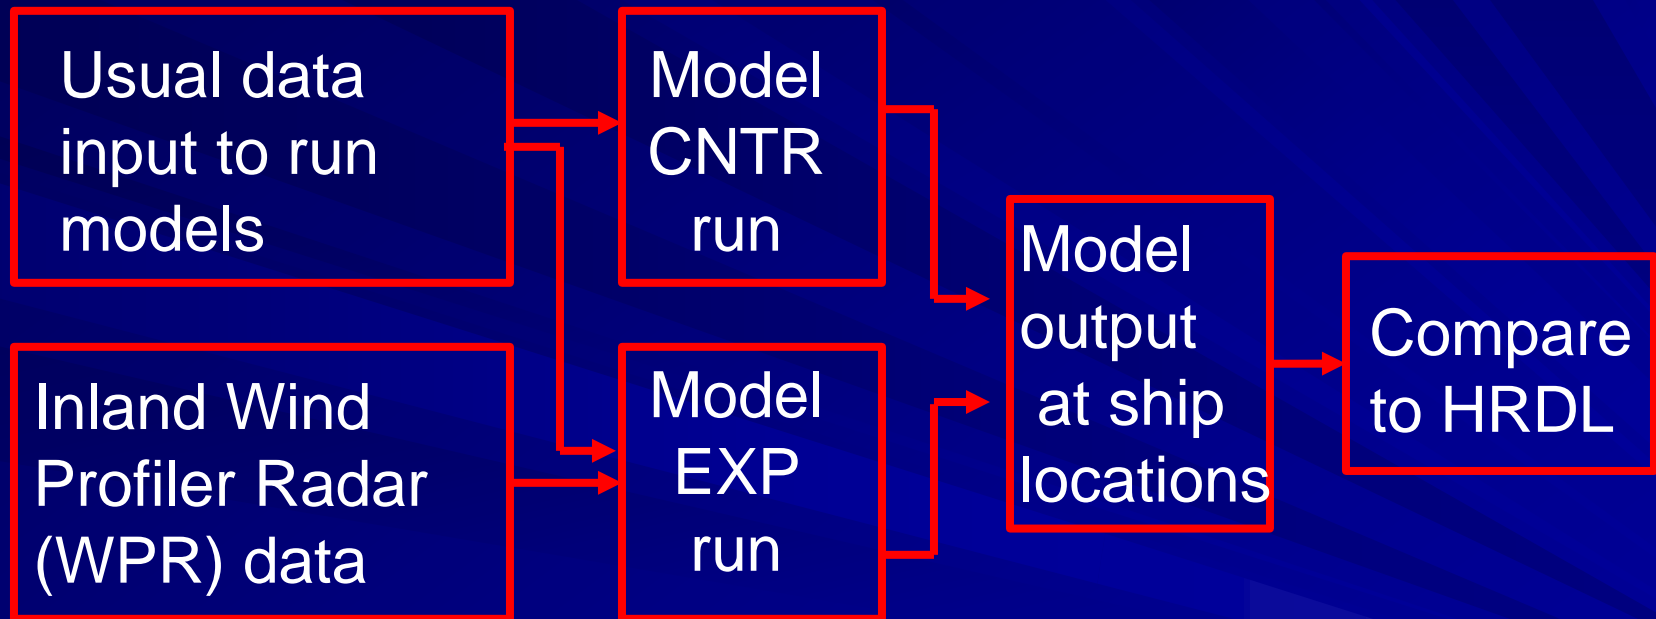

Ship tracks during two study periods

The model verification

Control run - without wind profiler data assimilation

Experimental run - with wind profiler data assimilation

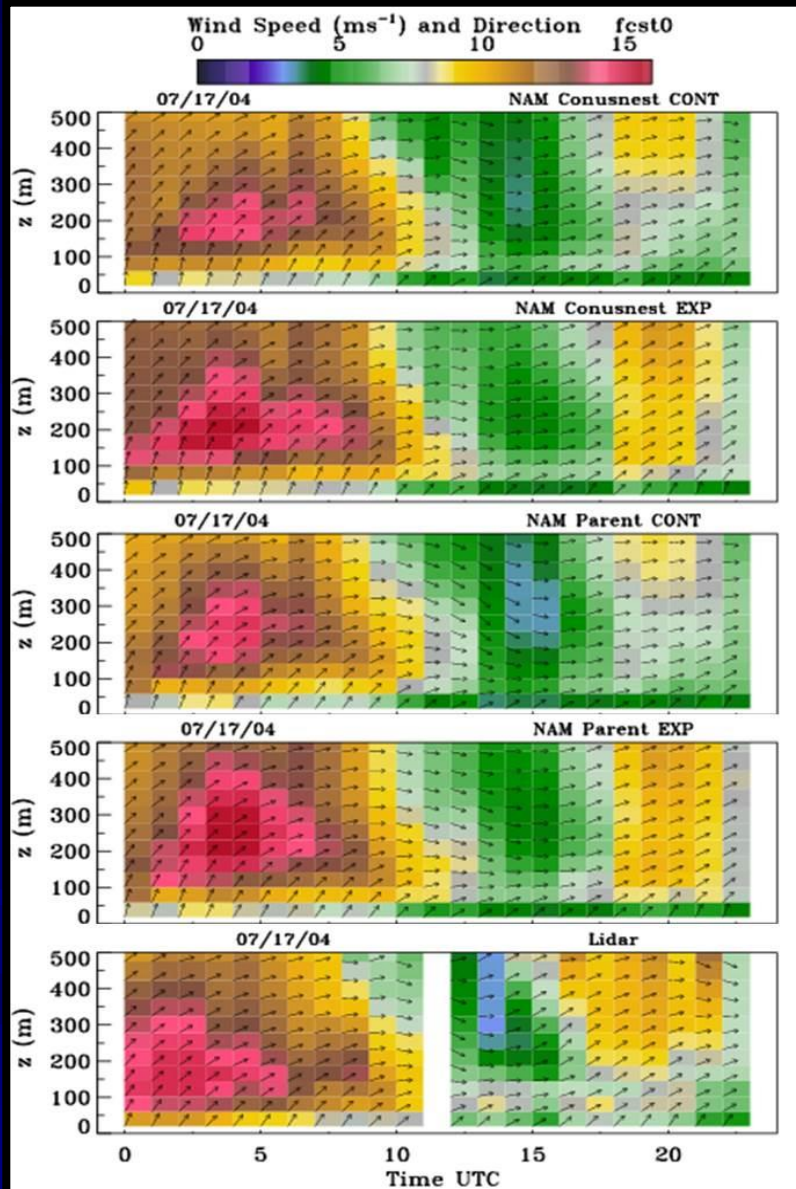

16 configurations (4 models x 2 runs x 2 periods)
were used to evaluate model skill in predicting
scalar and vector winds

Observed and modeled wind field

NAMRR CONT	1479	0.87	0.62 ± 0.12	0.71 ± 0.01

Greater discrepancies for stronger winds

Time-series of measured and observed wind at 80 m for several lead times

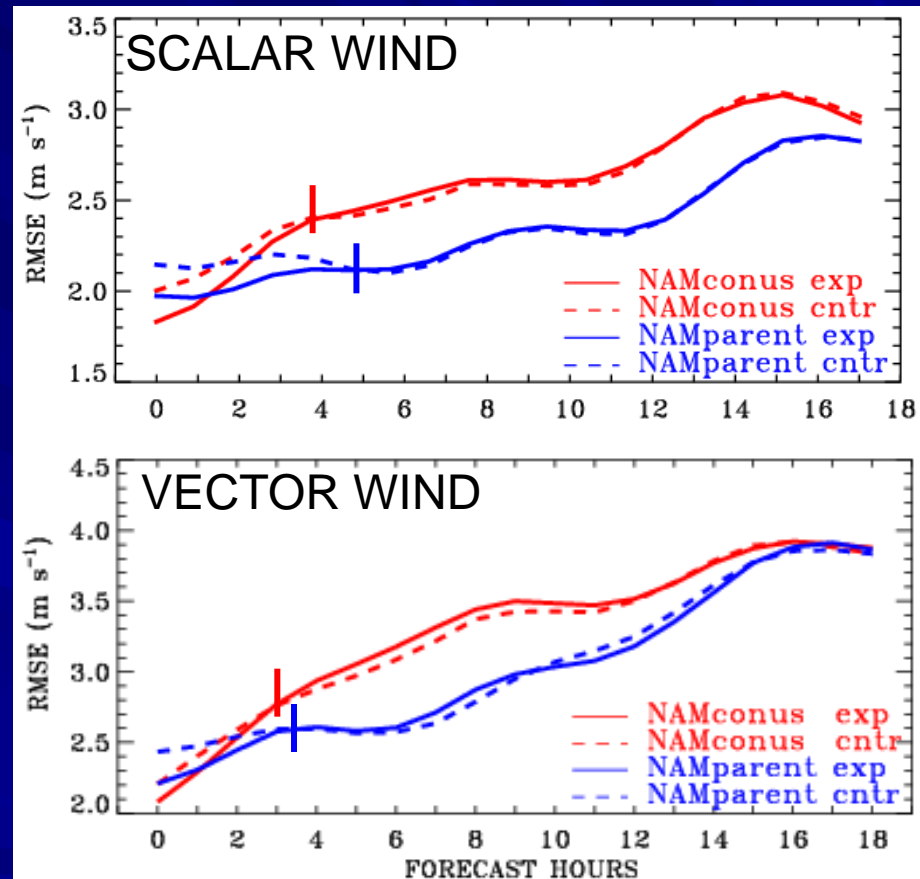

Note under prediction of nocturnal winds (03-04 UTC) for the 0-3 hr lead-time forecasts, and over prediction of the late afternoon winds (18-06 UTC) for the 6 and 12-hr forecasts.

RMSE between observed and modeled wind

Study period - August 6-12
up to 500 m layer

ESRL models

NCEP models

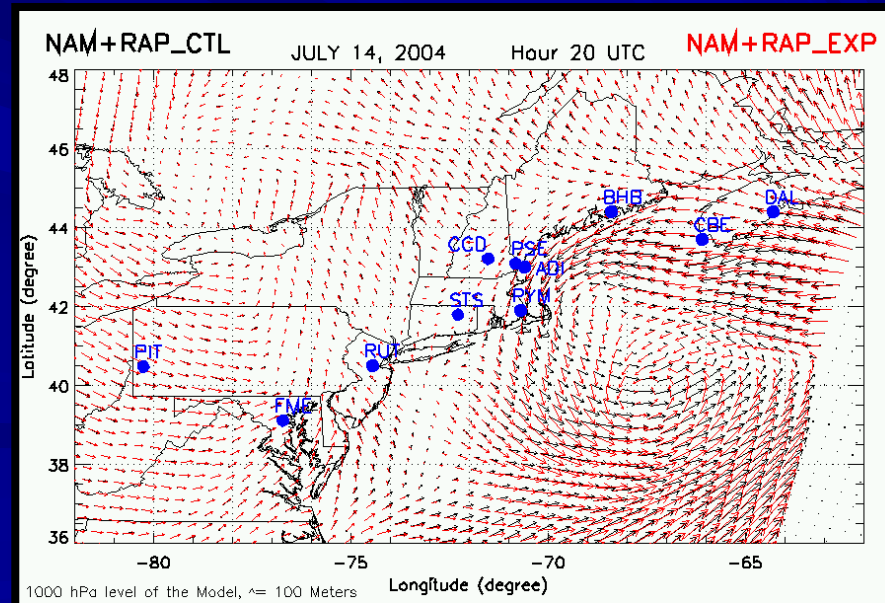

All models show an improvement for 3-5 lead hours
ESRL RAP shows an improvement up to 9 lead hours 19

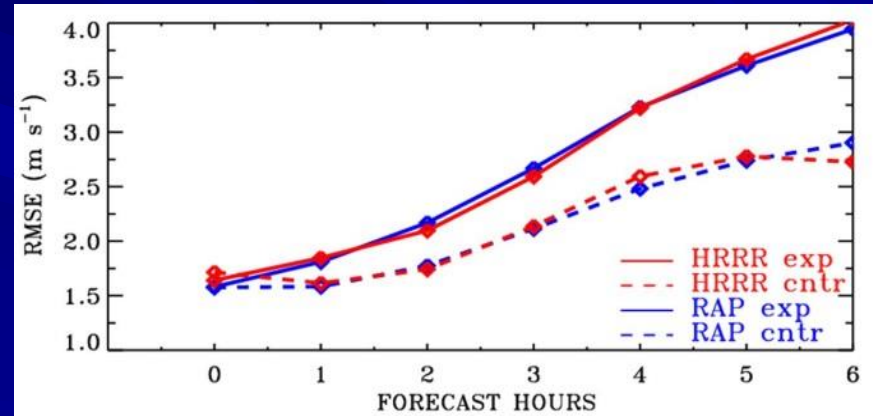

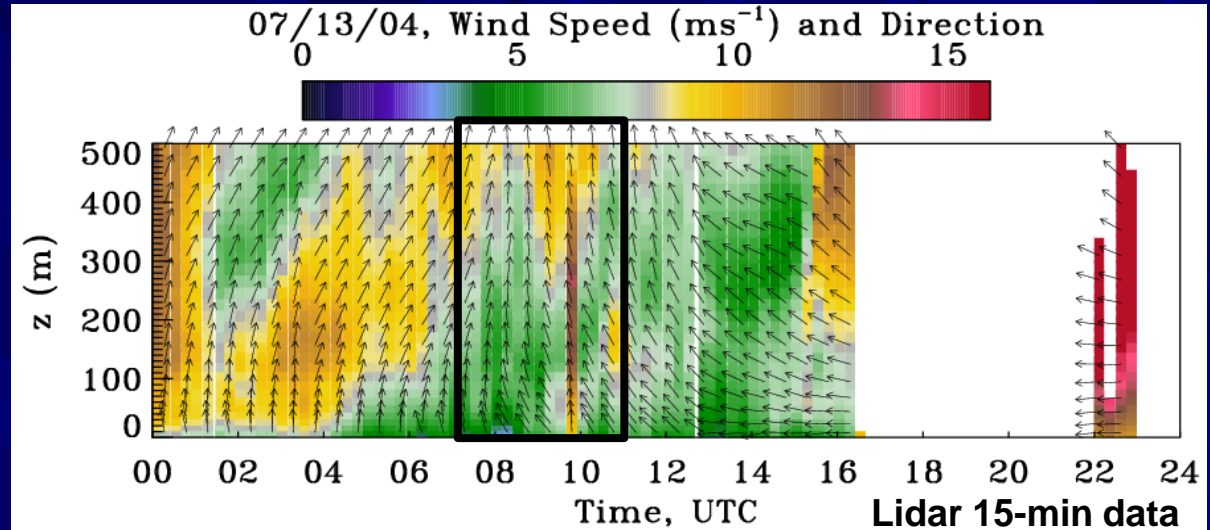

July 13-15 atmospheric conditions

- Fog and rain
- Change of wind direction
- Mesoscale low-pressure vortex

Case study: July 13 atmospheric conditions

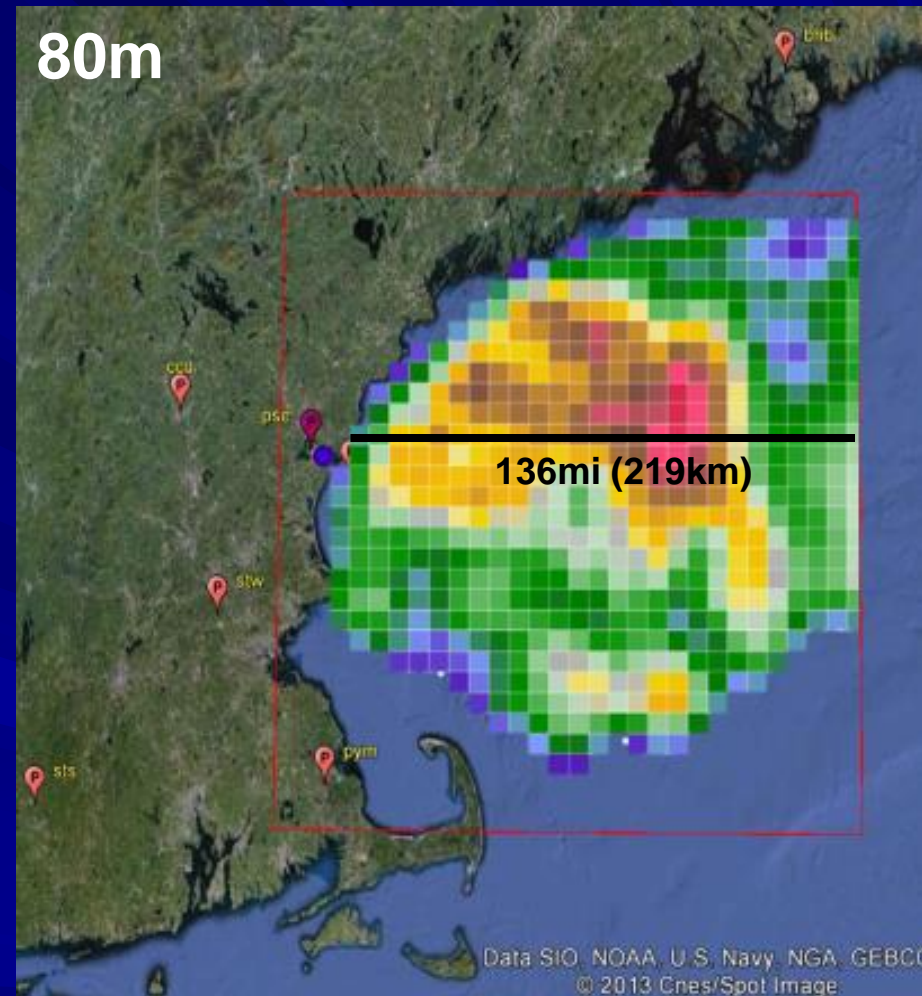

RMSE between HRDL-measured and modeled winds averaged in the first 500-m

Spatial Variability (August 11, 8 hours)

Could surface data represent hub-height winds?

July 9 - August 12, 2004

Spatial distribution of winds at surface differs from distribution at hub-height

Conclusions

- All models capture major trends in wind field
- Larger discrepancies in observed and modeled winds were found below 100-200m
- Assimilation of wind profilers data show up to 10% improvement in all models for the first 2-4 forecast hours
- All models show better agreement with lidar data for August period compared to July, when 3 days of fog, rain, and directional ramps were observed
 - Assimilation of wind profilers data for these days leads to greater RMSE.
- Short-term experiments provide insight on wind variability:
 - spatial, vertical, diurnal

WE-oriented, long-term measurements are needed to answer all questions !

Thank You!

Projected US offshore wind farms

- **Cape Wind** - off the coast of Massachusetts
130-turbines, ~ 420 MW
- **Long Island Offshore Wind Park**
off the coast of Long Island, New York
40 turbines, 140 MW
- **Off the Galveston**, Texas coast 50 turbines

Wind turbines projected for offshore installation will be larger than inland turbines

More wind Power Production

$$P \sim D V^3$$

Cape Wind 3.6 MW turbine:

79 m hub, 111 m D, 134.5 m above water

Proposed 10 MW turbine:

162 m hub, 145 m D, 234.5 m above water
(~30 story building)

Motion compensation

Stabilize the pointing of the beam

- Low elevation angle scans
- Vertical staring

Remove platform motion from

LOS velocity measurements

- Linear
- Rotational ($\omega \times r$)

Maintain “world frame” scan parameters

Pointing-angle accuracy tests

Land-based (in this building)
Triple-swiveling motorized platform to simulate roll, pitch, and yaw from ship motions, wave activity

2 tests on ship at sea:

- 1) Horizontal (0° elevation) azimuth scans (see horizon)
- 2) Track sun

Solar disk and cross hairs

Conclusion: Scanner maintains desired pointing angle to less than 0.5° under normal conditions, less than 1° in very rough seas

Power-law wind speed profile vs. measured

$$U = U_0 (Z/Z_0)^\alpha$$

07/30/04

Black - lidar
 dotted - $\alpha=1/7$
 solid - $\alpha=0.34$
 blue - $Z_0=15m$
 red - $Z_0=25m$
